DECLARATION

The work submitted in this dissertation is the result of my own investigation, except where otherwise stated.

It has not already been accepted for any degree, nor concurrently submitted for any other degree.

Abstract

In developing countries, post-harvest losses destroy about 15 -16 percent of the rice crop. This figure is even as much as 40 -50 percent in countries where there are challenging natural events and climatic conditions, such as regular heavy monsoons. Some stages in the rice post-harvest system are more critical than others, particularly drying and storage. Rice millers and farmers are beginning to understand and accept the need to invest in post-harvest technologies not only because these technologies are now affordable, but also because they offer the potential to increase profits by adding quality and commercial value to the final products. Placement of moisture in the paddy seed is critical while drying. Traditionally, human experts determine the temperature and duration of drying to keep the proper moisture distribution within the paddy seed. It is known that, properly dried paddy will yield much higher output after the hulling and milling process.

The major considerations of this design are reducing the quantitative and qualitative losses which could occur during the drying of parboiled paddy rice. This study includes the design of a temperature profile controlled LSU (Louisiana State University) type dryer with details of the methodology, and design of the components to detect moisture placement in paddy seed which could in turn used to determine the temperature and duration of drying.

A reduction of two percent of milling loss is achieved by temperature profile control. It is established that the moisture placement can be determined using capacitive and resistive moisture sensors. A correlation between capacitance and resistance to moisture placement in paddy is determined by carrying out trials with human experts. Linguistic variables and the actions taken to control temperature and drying time are established in this study. As further improvements a fuzzy logic based approach is discussed to simulate the human decisions.

Acknowledgement

Throughout my childhood I always dreamt of building something extraordinary, discovering something helpful to human being. During the past years it always kept on back of my mind. Now that the time has come, I have given the abilities, resources and the knowledge, it is time to revive. By passing this knowledge I gained by doing this research, I hope to improve the standards and profits of rice millers and farmers in Sri Lanka.

First of all, I would like to express my thanks to my supervisors, Dr. Harsha Abeykoon and Prof. Lanka Udawatta, for their great insights, perspectives and guidance. To Deputy Minister of Agriculture, Mr. Siripala Gamlath, for providing with information, advice and allowing to do testing and research at Nipuna rice mill, Katukelyawa, Minneriya. Without your help, I could not have finished this work. Sincere gratitude is also extended to those who serve in the Department of Electrical Engineering office and Post Graduate Office, Faculty of Engineering, University of Moratuwa, Sri Lanka and to numerous individuals including my colleagues for the assistance in various ways; you gave me support and encouragement to bring this academic activity to a success. I genuinely appreciate your support.

To my editor, my niece, Rangana Wanniarachchi, you gave me your valuable time in between your studies and finals. I truly value your time, I thank you.

To my parents, and my beloved family for always encouraging me to reach the highest, I thank you for being in my side always. Finally, to my wife Gayathri, and the children Haren and Yenuli for being patient with me when I am busy working, studying, I love you all.
