## ACKNOWLEDGMENT

First of all I would like to offer my deepest gratitude to my supervisor and the Head of the Department of Materials Engineering Dr. S. U. Adikary who granted the opportunity for me to do this research work and for his kind and valuable guidance at each stage of the project. The encouragement I received is greatly appreciated.

I take this opportunity to thank Dr. M. Jayaratne for the assistance given to me as the Research coordinator.

Then I deeply appreciate the encouragement and the corporation given to me by Mr. U.Gunawardena, who is the Managing Director, Ceracraft Pvt Ltd, Horana. I take this opportunity to thank him for part of the raw material supplied and providing production scale firing facilities. Also I am grateful for revising the English language of the manuscript.

I am very grateful to Mr. V.S.C. Weragoda, senior lecturer of Department of Materials Engineering for his kind support for thermal conductivity and mechanical testing during my research work

In addition to that, I like to express my thanks all the academic staff members of the Department of Materials Engineering, University of Moratuwa for their assistance and contribution to my research work.

I am indebted to National Science Foundation (NSF) for the awarding of a research grant to carry out my research successfully.

I am grateful to Mr. S.Chandrapala, Mr.Swaris and Mr.Abeyarathne and other non-academic staff members of the Department of Materials Engineering, for their assistance and contribution to my research work.

In conclusion, I would like to express my pardon if I have inadvertently omitted the name of those to whom thanks is due.

Jayawardane J.T.S.T

## ABSTRACT

This research work describes development of a glazed red clay cookware body with adequate thermal shock resistance. Two red clay deposits were investigated (Malwana and Hambanthota region) which are currently used for pottery industry. X-ray diffraction analysis (XRD), chemical analysis, differential thermal analysis (DTA) and scanning electron microscopic investigation (SEM) were used to determine the clay properties.

Thermal compatibility of red clay and different fritted glazes were investigated using thermal expansion and thermal shock resistance of individual body/glaze components. This investigation revealed that the coefficient of thermal expansion of red clay was lower than all tested glazes. Therefore it was difficult to formulate a suitable glaze to match the red clay body. Quartz was incorporated into red clay to increase the thermal expansion of the body. According to the results, thermal shock resistance decreased with increasing quartz content of the body. The thermal shock resistance and coefficient of thermal expansion of red clay body were investigated with different proportions of quartz as 10%, 20%, 30%, 35% and 40% at a firing temperature of 1050°C and isothermal holding time 30 minutes. The behaviours of the thermal conductivity, thermal shock resistance and important mechanical properties such as modulus of rupture and modulus of elasticity of each formulated body were studied. The results revealed that thermal conductivity increased with increasing quartz content of the body. Modulus of rupture and modulus of elasticity were decreased with increasing quartz content of the body.

Initially to preserve the red colour appearance of the product, it was decided to use a transparent glaze and three transparent glazes were investigated. Coefficients of thermal expansion of these transparent glazes were theoretically compatible with body composition having a quartz content of 30%. Actual size cookware samples were fabricated and required properties were tested under actual domestic conditions. But they were not successful on direct heating test. Body compositions with 35% and 40% quartz were investigated and they also gave the same results.

Hence it was necessary to develop a body with better thermal shock resistance having low quartz content. For this purpose glaze with low coefficient of thermal expansion was required and a semi matt glaze was selected by partially sacrificing the red colour appearance of the body.

Malwana red clay body with 25% quartz having a coefficient of thermal expansion  $60.31 \times 10^{-7} \text{ K}^{-1}$  and thermal shock resistance  $0.97 \text{ kJ m}^{-1} \text{ s}^{-1}$  and the glazes having coefficient of thermal expansion in the range of  $(49-51) \times 10^{-7} \text{ K}^{-1}$  and thermal shock resistance in the range of  $(1.10-1.20) \text{ kJ m}^{-1} \text{ s}^{-1}$  could be effectively used to manufacture a glazed red clay cookware product.

It can be concluded that a suitable body composition for glazed cookware production could be formulated by incorporating quartz in correct proportion to kaolinitic type red clay.
