ACKNOWLEDGEMENTS

Writing a dissertation is a challenging task and I wish to thank a number of people who helped me achieve this important milestone in my life.

First of all, I wish to express my heartfelt gratitude to my supervisor Dr. T.S.G. Peiris for all the advice and guidance provided and for the time and effort exerted on my behalf.

I greatly appreciate the support extended to me by the lecturers and staff of the Department of Mathematics during the course of my Masters degree.

I also wish to thank my parents, Professor Sucharita Gamlath and Mrs. Shantha Gamlath for looking after my daughter and supporting me to complete my Masters. A big thank you to Akki, Aparna and Sunil for easing my parents' burden during the long hours I spent away from home to attend lectures and write my dissertation.

My deepest appreciation goes forth to my husband Dr. Nishada Dahanayake for his untiring efforts to bring out the best in me always and having faith in my capabilities.

Our little daughter Divya also deserves special mention for bringing smiles and solace amidst all the pressure.

S. GAMLATH

ABSTRACT

The Human Development Index (HDI) constructed by the United Nations Development Programme (UNDP) is the most popular measure of human development. The HDI has undergone a substantial number of revisions over time, but in its current form, it is a measure made up of four variables: gross national income in constant purchasing parity dollars, life expectancy at birth, mean years of schooling and expected years of schooling. The first indicator measures the income facet of human development, the second indicator measures the health dimension and the third and fourth indicators measure the education dimension. Each variable is scaled to take a value between 0 and 1. The geometric mean of the scaled values of the two education indicators is defined as the education index. The geometric mean of the education index and the two other variables is taken as the HDI value for a given country. In 2011, based on the values of the above HDI, 187 countries were ranked and grouped into four categories.

In spite of its simplicity, popularity and wide acceptability, a number of authors have noted some major shortcomings of the UNDP's HDI such as: the narrowness of scope, the arbitrary nature in which weights are attached to different dimensions, the unreliability of data used in computations and the inability to compare HDI results over time due to frequent revisions to the composition and construction methodology. Upon looking these shortcomings the present study identified 17 new variables in addition to the four variables currently used to develop an alternative HDI to broaden the dimensions of human development measured.

Upon carrying out Principal Components Analysis (PCA), these 21 variables were reduced to 13 variables which were deemed to be adequate for the purpose of measuring human development effectively. Thereafter, two alternative indices were constructed by applying PCA and Factor Analysis (FA) to this system of 13 variables.

Under PCA, two PCs, the first accounting for 71% and the second accounting for 12% of the variance of the 13 variables were identified. Since the first PC constituted of all the variables with similar weights and the same sign, it was considered as an appropriate index for

measuring human development. The validity of PCA was confirmed using jack-knife validation. Countries experiencing notable changes in rank were identified and possible explanations for these changes were sought. Another ranking was obtained using FA. The system of 13 variables could be represented by two latent factors accounting for 83% of the total variance. The structure of the factor solution was confirmed under different extraction and rotation methods. Since the first factor loaded mainly on the governance indicators while the second factor loaded on the health, education, income and female empowerment dimensions, a country score with a weight of 0.2 on the first factor and a weight of 0.8 on the second factor was computed to reflect the number of dimensions each factor captured. These changes were investigated for each group and possible reasons for these changes were outlined and these changes were also analyzed in the light of additional background information about the countries in question. The rankings under factor analysis displayed a higher correlation of 0.973 with HDI ranks when compared to the correlation of 0.953 that the ranks obtained under the principal components analysis displayed with the HDI. These country scores too led to considerable changes in the ranks of many countries when compared to HDI ranks in every group, and an analysis similar to that carried out for changes in rank under PCA, and a comparison of the ranks obtained under the PCA and FA was carried out.

The rankings obtained under FA were regarded as better than the rankings obtained under principal components analysis, since the loadings obtained were higher and the weights in the country scores under FA reflected the importance of each dimension more effectively than the scores obtained under PCA. Upon recognizing the various shortcomings the study suffers from such as unreliability and inaccuracies in the data, the use of certain subjective indicators for developing the alternative indices and the non-use of oblique rotations when conducting FA, the study recommended the potential for broadening the scope of the HDI to include at least some of the variables identified in the study.

Keywords: Human Development Index, Principal Components Analysis, Factor Analysis, governance indicator.
